

BIFURCATION SET OF MULTI-PARAMETER FAMILIES OF COMPLEX CURVES

CEZAR JOIȚA AND MIHAI TIBĂR

ABSTRACT. The problem of detecting the bifurcation set of polynomial mappings $\mathbb{C}^m \rightarrow \mathbb{C}^k$, $m \geq 2$, $m \geq k \geq 1$, has been solved in the case $m = 2$, $k = 1$ only. Its solution, which goes back to the 1970s, involves the non-constancy of the Euler characteristic of fibres. We provide a complete answer to the general case $m = k + 1 \geq 3$ in terms of the Betti numbers of fibres and of a vanishing phenomenon discovered in the late 1990s in the real setting.

1. INTRODUCTION

The bifurcation locus of a polynomial map $F : \mathbb{C}^m \rightarrow \mathbb{C}^k$ with $m \geq k$, i.e. the minimal set of points $B(F) \subset \mathbb{C}^k$ outside which the mapping is a C^∞ locally trivial fibration, is an algebraic set of dimension at most $k - 1$ (cf [KOS], [DRT] etc). The following result was found in the 1970's by Suzuki [Su], and later also by Hà and Lê in [HL]: *Let $f : \mathbb{C}^2 \rightarrow \mathbb{C}$ be a polynomial function and let $\lambda \in \mathbb{C} \setminus f(\text{Sing } f)$. Then λ is not a bifurcation value at infinity if and only if the Euler characteristic of the fibres $\chi(f^{-1}(t))$ is constant for t varying in some neighborhood of λ .* For polynomial functions of more than 2 variables, the existence of bifurcation values which are regular might be due to the variation of Euler characteristic of fibres under certain supplementary assumptions, but it was shown that this is not true for any such polynomial function.

It turns out that the Euler test is also not anymore sufficient if we replace \mathbb{C}^2 by an affine surface, cf examples by Zaidenberg [Za1] and Gurjar and Miyanishi [GM], or in case of polynomial maps with $m > k \geq 2$. This led to the natural question, of which we have learned in 2012 from Gurjar, whether instead of Euler characteristic, the constancy of the Betti numbers of the fibers was sufficient to insure topological triviality in case of regular fibres of polynomial maps $\mathbb{C}^{n+1} \rightarrow \mathbb{C}^n$, $n \geq 2$.

We show here how to detect the regular bifurcation values of polynomial maps $F : \mathbb{C}^{n+1} \rightarrow \mathbb{C}^n$, $n \geq 2$. We first give an example (at §1.1 below) demonstrating that the constancy of the Betti numbers of the fibers in the neighborhood of a regular value λ is not sufficient for $\lambda \notin B(F)$. We then prove that the constancy of the Euler characteristic together with a certain non-vanishing condition yield the following natural necessary and sufficient criterion:

Theorem 1.1. *Let $F : \mathbb{C}^{n+1} \rightarrow \mathbb{C}^n$ be a polynomial map. Let λ be a point in the interior of the set $\text{Im } F \setminus \overline{F(\text{Sing } F)} \subset \mathbb{C}^n$. Then $\lambda \notin B(F)$ if and only if the Euler characteristic*

of the fibres $F^{-1}(t)$ is constant for t varying in some neighborhood of λ and no connected component of $F^{-1}(t)$ is vanishing at infinity as $t \rightarrow \lambda$.

To define “vanishing components”, we consider the more general situation of a holomorphic map $p : M \rightarrow B$ between connected complex manifolds with $\dim M = \dim B + 1$, and let $\lambda \in \text{Im } p$ be a regular value of p . The fiber $p^{-1}(t)$ is a complex manifold of dimension 1 and may be not connected; we assume that it has finitely many connected components. We then denote by C_t some connected component of the fiber $p^{-1}(t)$.

Definition 1.2. We say that there are *vanishing components at infinity* when t tends to λ if there is a sequence of points $t_k \in B$, $t_k \rightarrow \lambda$ such that for some choice of a connected component C_{t_k} of $p^{-1}(t_k)$ the sequence of sets $\{C_{t_k}\}_{k \in \mathbb{N}}$ is *locally finite*, i.e., for any compact $K \subset M$, there is an integer $p_K \in \mathbb{N}$ such that $\forall q \geq p_K$, $C_{t_q} \cap K = \emptyset$.

If there is no vanishing at infinity at λ then we say that *no connected component of $p^{-1}(t)$ is vanishing at infinity when $t \rightarrow \lambda$* , or simply that *one has the property (NV) at λ* .

A more effective way to define (NV) is as follows: we denote by M_b the fibre $p^{-1}(b)$. Let $M_b = \sqcup_j M_b^j$ be the decomposition of the fibre M_b into connected components. Let also $\varphi : M \rightarrow \mathbb{R}$ be a continuous exhaustion function, i.e. $\{x \in M : \varphi(x) \leq r\}$ is compact for every $r \in \mathbb{R}$ (for example, if $M = \mathbb{C}^n$, one we may take $\varphi(x) = \|x\|$). We define:

$$\mu(b) := \max_j \inf_{x \in M_b^j} \varphi(x)$$

Then “vanishing component at infinity when $t \rightarrow \lambda$ ” means that there exists a sequence of points $t_k \in B$, $t_k \rightarrow \lambda$, such that $\lim_{k \rightarrow \infty} \mu(t_k) = \infty$.

The phenomenon of “vanishing of components” has been studied in the real setting of polynomials $\mathbb{R}^2 \rightarrow \mathbb{R}$ in [TZ] and more generally in [JT]. It turns out that this is related to the “vanishing cycles” and “emerging cycles” introduced for independent reasons by Meigniez [Me1], [Me2]. In another stream, “vanishing cycles at infinity” have been studied in the context of complex polynomial functions in [Pa], [ST1], [ST2], [Ti1], [Ti2] etc.

A polynomial map $\mathbb{C}^3 \rightarrow \mathbb{C}^2$ with vanishing components and constancy of the Euler characteristic of regular fibres was produced in [HN, Remark 2.3].

Yet another phenomenon which may occur is the “splitting at infinity at λ ” (in the terminology of [TZ, JT]) when approaching the bifurcation value λ . The simplest example is the complex polynomial $f(x, y) = x + x^2 y$. It was shown in the real setting [TZ, Example 3.1] that these two phenomena may happen simultaneously while the Betti numbers are locally constant. We present here an example in the complex setting where both phenomena occur. It proves at the same time that the non-vanishing hypothesis of Theorem 1.1 is necessary.

1.1. Main example. Let $F : \mathbb{C}^3 \rightarrow \mathbb{C}^2$ be defined by

$$F(x, y, z) = (x, [(x-1)(xz+y^2)+1][x(xz+y^2)-1]).$$

The singular locus of F is the union of the z -axis, a curve and a surface, the last two having the same image by F . One then checks that $(0, 0)$ is an interior point of $\mathbb{C}^2 \setminus \text{Sing } f$.

If $(a, b) \in \mathbb{C}^2$ is close enough to $(0, 0)$ and $a \neq 0$ then $f^{-1}(a, b) = \{(x, y, z) \in \mathbb{C}^3 \mid x = a, az + y^2 = c_1\} \cup \{(x, y, z) \in \mathbb{C}^3 \mid x = a, az + y^2 = c_2\}$ where c_1 and c_2 are the two

distinct roots of the equation $[(a-1)\lambda + 1][a\lambda - 1] = a(a-1)\lambda^2 + \lambda - 1 = b$. Therefore $f^{-1}(a, b) \simeq \mathbb{C} \sqcup \mathbb{C}$.

If $a = 0$ and b is close enough to zero then $f^{-1}(0, b) = \{(x, y, z) \in \mathbb{C}^3 \mid x = 0, y = d_1\} \cup \{(x, y, z) \in \mathbb{C}^3 \mid x = 0, y = d_2\}$ where d_1 and d_2 are the two roots of $y^2 = b^2 + 1$; thus $f^{-1}(a, b) \simeq \mathbb{C} \sqcup \mathbb{C}$.

All fibers of f in a small neighborhood of $(0, 0) \in \mathbb{C}^2$ have therefore exactly two connected components isomorphic to \mathbb{C} . On the other hand, when $a \rightarrow 0$ one component vanishes at infinity and the other one splits into two copies of \mathbb{C} , which shows that f is not locally trivial at $(0, 0)$ whereas its fibres are abstractly diffeomorphic and even isomorphic.

In order to prove Theorem 1.1 we show the following more general result:

Theorem 1.3. *Let $p : M \rightarrow B$ be a holomorphic map between connected complex manifolds, where M is Stein and $\dim M = \dim B + 1$. We assume that the Betti numbers $b_0(t)$ and $b_1(t)$ of all the fibers $p^{-1}(t)$ are finite. Let λ be a point in the interior of the set $\text{Im } p \setminus \overline{p(\text{Sing } p)} \subset B$. Then $\lambda \notin B(p)$ if and only if the Euler characteristic of the fibres is constant for t varying in some neighborhood of λ and no connected component of $p^{-1}(t)$ is vanishing at infinity when $t \rightarrow \lambda$.*

This is in turn based on the following result for connected fibres, the proof of which relies on deep results by Ilyashenko [Il1, Il2] and Meigniez [Me2].

Theorem 1.4. *Let $p : M \rightarrow B$ be a holomorphic map between connected complex manifolds which is a submersion, where M is Stein with $\dim M = \dim B + 1$. Assume that all the fibres of p are connected and have the same finite first Betti number $b_1 < \infty$.*

Then p is a trivial fibration.

The condition of non-vanishing components at infinity is then employed in order to reduce the general case to Theorem 1.4.

We also note the following by-product of Theorem 1.4 in the case of regular functions on affine surfaces, which is a small part of a result proved by Zaidenberg [Za1, Lemma 3.2]: *Let $f : X \rightarrow C$ be a primitive function from an affine surface X to a curve C . A regular value $\lambda \in C$ is a bifurcation value of f if and only if the fibre $f^{-1}(\lambda)$ is not diffeomorphic to the general fibre of f .*

An example of a non-primitive function with regular values in some neighborhood of 0 and where the fibres are isomorphic, but which is not a fibration is the following: let $X \subset \mathbb{C}^3$ be the surface given by the equation $[(x-1)(xz+y^2)+1][x(xz+y^2)-1]=0$ in the above example §1.1, let $f : X \rightarrow \mathbb{C}$ be the restriction of the linear form $l = x$ on \mathbb{C}^3 .

2. PROOF OF THEOREM 1.4

2.1. Preliminary facts. We recall basic definitions, see e.g. [Ho], and two results that we shall need:

Definition 2.1. (a). A complex manifold X is called *Stein* if there exists a smooth strictly plurisubharmonic exhaustion function $\varphi : X \rightarrow \mathbb{R}$.

(b). Suppose that X is a Stein complex manifold and D is a Stein open subset of X . Then D is called *Runge in X* if the restriction morphism $\mathcal{O}(X) \rightarrow \mathcal{O}(D)$ has dense image in the topology of uniform convergence on compacts.

Proposition 2.2. [Na2] *If X is a Stein manifold and $\varphi : X \rightarrow \mathbb{R}$ is a continuous plurisubharmonic function, then for every $R > 0$, the open subset of X defined by $\{x \in X \mid \varphi(x) < R\}$ is Stein and Runge in X .* \square

Proposition 2.3. ¹[BS] *If \mathcal{S} is an open Riemann surface and D is an open subset, then D is Runge in \mathcal{S} if and only if the morphism $H_1(D, G) \rightarrow H_1(\mathcal{S}, G)$ induced by the inclusion $D \hookrightarrow \mathcal{S}$ is injective for any abelian group G .* \square

We prove the following key semi-continuity result:

Proposition 2.4. *Let $p : M \rightarrow B$ be a holomorphic submersion, where M and B are connected complex manifolds and $\dim M = \dim B + 1$. Assume that:*

- (a) *M is Stein, and*
- (b) *the Betti numbers $b_0(t)$ and $b_1(t)$ of the fiber $p^{-1}(t)$ are finite for all $t \in B$.*

Then the top Betti number $b_1(t)$ is lower semi-continuous.

This looks similar to semi-continuity results proved in case of families of hypersurfaces in [ST3], [ST4, Prop. 2.1], however the method of proof is totally different.

Proof of Proposition 2.4. Let $\mathcal{C}_\lambda = \{C_1, C_2, \dots, C_{b_0}\}$ denote the set of connected components of the fibre $p^{-1}(\lambda)$, where $b_0 := b_0(\lambda)$, for some fixed value $\lambda \in B$.

Let $f : M \rightarrow \mathbb{C}$ be a holomorphic function such that $f|_{C_j} \equiv 2j$, for any $j \in \{1, \dots, b_0\}$. Such functions do exist because M is Stein, see e.g. [Ho, Theorem 7.4.8]. We define the following disjoint open subsets of M :

$U_1 = \{x \in M \mid \operatorname{Re}(f(x)) < 3\}$, $U_j = \{x \in M \mid 2j - 1 < \operatorname{Re}(f(x)) < 2j + 1\}$ for $j \in \{2, \dots, b_0 - 1\}$, $U_{b_0} = \{x \in M \mid \operatorname{Re}(f(x)) > 2b_0 + 1\}$, where $\operatorname{Re}(f)$ denotes the real part of f . It follows that U_j is Stein, that U_j is Runge in M , and that $C_j \subset U_j$, for any $j \leq b_0$.

One can find a compact connected subset W_j of C_j such that inclusion $W_j \hookrightarrow C_j$ induces a surjective morphism $H_1(W_j, \mathbb{Q}) \rightarrow H_1(C_j, \mathbb{Q})$ (e.g. by choosing a finite set of compact geometric generators of $H_1(C_j, \mathbb{Q})$ and some connected compact W_j containing all of them).

Next, there exists a smooth strictly plurisubharmonic exhaustion function $\varphi_j : U_j \rightarrow \mathbb{R}$ and a sufficiently large real number $r_j \gg 1$ such that $\mathbb{B}_j := \{y \in U_j \mid \varphi_j(y) < r_j\}$ contains \overline{W}_j , its boundary $\partial \mathbb{B}_j$ is non-singular at every point of $\mathbb{B}_j \cap C_j$ and it intersects C_j transversely.

We may choose φ_j such that $\mathbb{B}_j \cap C_j$ is moreover connected. Indeed, let Ω_j be the connected component of $\mathbb{B}_j \cap C_j$ which contains W_j , and let $s_j = \min_{x \in C_j} \varphi_j(x)$, which exists since φ_j is an exhaustion. We know that Ω_j has smooth boundary. It also follows that Ω_j is Runge in C_j and, since C_j is a smooth complex curve, that $\overline{\Omega}_j$ is holomorphically convex in C_j and hence in U_j . This last statement follows from the definition and Theorem 7.4.8 in [Ho]. We may choose (see e.g. [Ho, Theorem 2.6.11]) a smooth plurisubharmonic function $\psi_j : U_j \rightarrow [0, \infty)$ such that $\psi_j = 0$ over a neighborhood of $\overline{\Omega}_j$ and $\psi_j \geq r_j - s_j + 1$ over the closure of $(\mathbb{B}_j \cap C_j) \setminus \Omega_j$. We have $\{y \in C_j \mid \varphi_j(y) + \psi_j(y) < r_j\} = \Omega_j$, hence replacing φ_j by $\varphi_j + \psi_j$ we get the claimed additional property.

¹has been extended to singular complex spaces of dimension 1 in [Mi].

By Proposition 2.2, \mathbb{B}_j is Runge in U_j and therefore $\mathbb{B}_j \cap C_j$ is Runge in C_j . It then follows from Proposition 2.3 that the inclusion $\mathbb{B}_j \cap C_j \hookrightarrow C_j$ induces an injective morphism $H_1(\mathbb{B}_j \cap C_j, \mathbb{Q}) \rightarrow H_1(C_j, \mathbb{Q})$. As $W_j \subset \mathbb{B}_j$ and $H_1(W_j, \mathbb{Q}) \rightarrow H_1(C_j, \mathbb{Q})$ is surjective, we deduce that $H_1(\mathbb{B}_j \cap C_j, \mathbb{Q}) \rightarrow H_1(C_j, \mathbb{Q})$ is in fact an isomorphism.

By Ehresmann's fibration theorem, there exists some small enough connected open ball $B' \subset \bigcap_{j=1}^{b_0} p(U_j) \subset B$ of λ such that the restriction:

$$(1) \quad p| : p^{-1}(B') \cap \mathbb{B}_j \rightarrow B'$$

is a trivial C^∞ -fibration.

Let us fix some $t \in B'$ and let $\mathcal{C}_t = \{\Gamma_1, \dots, \Gamma_q\}$ be the set of connected components of $p^{-1}(t)$. We define $\beta : \mathcal{C}_\lambda \rightarrow \mathcal{C}_t$ by $\beta(C_j) =$ the unique connected component of \mathcal{C}_t which intersects \mathbb{B}_j . By changing the indices we may assume that $\beta(C_1) = \dots = \beta(C_{n_1}) = \Gamma_1, \dots, \beta(C_{n_{q'}+1}) = \dots = \beta(C_{b_0}) = \Gamma_{q'}$ where $q' \leq q$ and $1 \leq n_1 < n_2 < \dots < n_{q'} < b_0$.

From the triviality of (1) it follows that, for $1 \leq j \leq n_1$, we have:

$$(2) \quad \dim H_1(\mathbb{B}_j \cap \Gamma_1, \mathbb{Q}) = \dim H_1(\mathbb{B}_j \cap C_j, \mathbb{Q}) = \dim H_1(C_j, \mathbb{Q}).$$

Since $\mathbb{B}_j \cap \Gamma_1$ is Runge in $U_j \cap \Gamma_1$ and since the later is Runge in Γ_1 , it follows that $\mathbb{B}_j \cap \Gamma_1$ is Runge in Γ_1 .

We need now Narasimhan's result [Na1, Lemma 1] which says that if X is a Stein space and X_1, X_2 are two disjoint Runge open subsets of X then $X_1 \cup X_2$ is Runge in X if and only if any two compact subsets $K_1 \subset X_1, K_2 \subset X_2$ can be separated by the real part of a holomorphic function $f \in \mathcal{O}(X)$.

By applying [Na1, Lemma 1] we get that the union $\bigcup_{j=1}^{n_1} \mathbb{B}_j \cap \Gamma_1$ is Runge in Γ_1 . By Proposition 2.2, the inclusion induces a monomorphism $H_1\left(\bigcup_{j=1}^{n_1} \mathbb{B}_j \cap \Gamma_1, \mathbb{Q}\right) \rightarrow H_1(\Gamma_1, \mathbb{Q})$, which implies that $\dim H_1(\Gamma_1, \mathbb{Q}) \geq \sum_{j=1}^{n_1} \dim H_1(C_j, \mathbb{Q})$. Repeating this argument for $\Gamma_2, \dots, \Gamma_{q'}$ and summing up the inequalities we obtain that $\sum_{j=1}^{q'} \dim H_1(\Gamma_j, \mathbb{Q}) \geq b_1(\lambda)$, which implies the inequality $b_1(t) \geq b_1(\lambda)$. \square

2.2. Coverings. Our starting point is the following key theorem by Y. S. Ilyashenko:

Theorem 2.5. [I1], [I2] *Let M be a Stein manifold foliated by complex curves, let \widehat{B} be a transversal cross-section and let \mathcal{F}_x denote the leaf of the foliation which contains the point $x \in B$.*

Then there exists a complex manifold \widetilde{M} together with a locally biholomorphic map $\pi : \widetilde{M} \rightarrow M$ such that the restriction $\pi| : \pi^{-1}(\mathcal{F}_x) \rightarrow \mathcal{F}_x$ is the universal covering of \mathcal{F}_x with base point x , for any $x \in B$.

Definition 2.6. In the setting of Theorem 1.4, let us consider the foliation defined by the fibres of the submersion $p : M \rightarrow B$ and the cross-section \widehat{B} defined by some lift by p of the base B . Let us denote by \widehat{x} the point of \widehat{B} which corresponds to $x \in B$ by the identification of \widehat{B} with B .

By applying Theorem 2.5 to this setting we obtain the manifold \widetilde{M} and the locally biholomorphic map $\pi : \widetilde{M} \rightarrow M$. We then have:

Proposition 2.7. *The map $\pi : \widetilde{M} \rightarrow M$ is a covering.*

Proof. Let us fix some point $x \in M$ and denote $M_b := p^{-1}(b)$, for $b \in B$. As in the proof of Proposition 2.4, we choose a compact connected subset W of $M_{p(x)}$ containing $\widehat{p(x)}$ such that inclusion $W \hookrightarrow M_{p(x)}$ induces a surjective morphism $H_1(W, \mathbb{Q}) \rightarrow H_1(M_{p(x)}, \mathbb{Q})$.

Since M is Stein, there is a strictly plurisubharmonic exhaustion function $\varphi : M \rightarrow \mathbb{R}$ and a sufficiently large real number $R \gg 1$ such that the boundary $\partial\{y \in M \mid \varphi(y) \leq R\}$ intersects the fiber $M_{p(x)}$ transversely, that $W \subset \{y \in M_{p(x)} \mid \varphi(y) < R\}$. Moreover, as in the proof of Proposition 2.4, we may assume that $\{y \in M_{p(x)} \mid \varphi(y) < R\}$ is connected. For $b \in B$ we denote:

$$M_{b,R} := M_b \cap \{y \in M \mid \varphi(y) < R\}.$$

By Propositions 2.2 and 2.3 and the inclusion $W \subset M_{p(x),R}$ we deduce that the inclusion $M_{p(x),R} \hookrightarrow M_{p(x)}$ induces an isomorphism $H_1(M_{p(x),R}, \mathbb{Q}) \simeq H_1(M_{p(x)}, \mathbb{Q})$.

By Ehresmann's fibration theorem, there exists a small connected open neighborhood $B' \subset B$ of $p(x)$ such that the restriction $p| : p^{-1}(B') \cap \{y \in M \mid \varphi(y) < R\} \rightarrow B'$ is a trivial C^∞ -fibration. Consequently, for any $b \in B'$, we have the isomorphism:

$$(3) \quad H_1(M_{b,R}, \mathbb{Q}) \simeq H_1(M_{p(x),R}, \mathbb{Q}).$$

Again by Propositions 2.2 and 2.3 we deduce that for $b \in B'$ the inclusion $M_{b,R} \hookrightarrow M_b$ induces an injective map $H_1(M_{b,R}, \mathbb{Q}) \rightarrow H_1(M_b, \mathbb{Q})$.

According to our hypothesis, $\dim H_1(M_{p(x)}, \mathbb{Q}) = \dim H_1(M_b, \mathbb{Q})$ and hence by (3) we get for all $b \in B'$:

$$\dim H_1(M_{b,R}, \mathbb{Q}) = \dim H_1(M_{p(x),R}, \mathbb{Q}) = \dim H_1(M_{p(x)}, \mathbb{Q}) = \dim H_1(M_b, \mathbb{Q})$$

and that the isomorphism $H_1(M_{b,R}, \mathbb{Q}) \simeq H_1(M_b, \mathbb{Q})$ is induced by the inclusion.

Lemma 2.8. *The inclusion $M_{b,R} \hookrightarrow M_b$ induces an isomorphism $\pi_1(M_{b,R}) \rightarrow \pi_1(M_b)$, for any $b \in B'$.*

Proof. As we have assumed that $M_{p(x),R}$ is connected and $p| : p^{-1}(B') \cap \{y \in M \mid \varphi(y) < R\} \rightarrow B'$ is a trivial fibration, it follows that the open set $M_{b,R}$ is connected, for any $b \in B'$. By a Mayer-Vietoris argument using the finite dimensional homology groups of M_b and $M_{b,R}$ we show that the set $M_b \setminus M_{b,R}$ is a disjoint union of finitely many cylinders, more precisely collars over the boundary components of $\partial \overline{M_{b,R}}$, which are just circles. By retracting the collars to their boundaries we get that $M_{b,R}$ is a deformation retract of M_b . \square

2.3. Following of the proof of Proposition 2.7. Let us recall Ilyashenko's construction [II1] of \widetilde{M} for our foliation defined by the fibres of p .

For each $x \in M$, a point in $\pi^{-1}(x) \subset \widetilde{M}$ is by definition an equivalence class of paths $\gamma : [0, 1] \rightarrow M_{p(x)}$ with fixed ends: $\gamma(0) = \widehat{p(x)}$, $\gamma(1) = x$. The topology of \widetilde{M} is defined as follows. For some point $\tilde{x} \in \widetilde{M}$, let $x := \pi(\tilde{x})$ and choose a path $\gamma : [0, 1] \rightarrow M_{p(x)}$ from $\widehat{p(x)}$ to x such that $\tilde{x} = [\gamma]$. By considering a tubular neighborhood of $\text{Im } \gamma$ on which p is a submersion and Ehresmann's theorem can be applied, there exists an open neighborhood V of x such that there exists a continuous function $g : V \times [0, 1] \rightarrow M$ with the following properties:

- $g(x, t) = \gamma(t)$ for any $t \in [0, 1]$,

- $g(y, t) \in M_{p(y)}$ for any $y \in V$ and $t \in [0, 1]$,
 - $g(y, 1) = y$ and $g(y, 0) = \widehat{p(y)}$ for any $y \in V$.
- Denoting $\gamma_y(t) := g(y, t)$, one has by definition that:

$$(4) \quad \widetilde{V}_g := \{[\gamma_y] \mid y \in V\}$$

is an open neighborhood of \tilde{x} and that the restriction $\pi| : \widetilde{V}_g \rightarrow V$ is a homeomorphism, where the homotopy class $[\gamma_y]$ is considered in $M_{p(x)}$ and $rel(0, 1)$.

Let now $U_0 \subset M_{p(x), R}$ be a small enough contractible neighborhood of x and consider a contraction $H : U_0 \times [0, 1] \rightarrow U_0$, i.e. $H(y, 0) = y$, $H(y, 1) = x$, $H(x, t) = x$ for $y \in U_0$ and $t \in [0, 1]$. Let

$$(5) \quad G = (G_1, G_2) : p^{-1}(B') \cap \{y \in M \mid \varphi(y) < R\} \rightarrow M_{p(x)} \times B'$$

be a diffeomorphism such that $G_2 = p$, $G(y) = (y, p(x))$ for each $y \in M_{p(x), R}$, and $G(\hat{y}) = (\widehat{p(x)}, y)$ for each $y \in B'$.

Let then $U := G^{-1}(U_0 \times B')$ be our neighborhood of x in M , where G is the diffeomorphism defined at (5). We show in the following that U is evenly covered by π .

So let $\tilde{x} \in \pi^{-1}(x)$. Since we know that $\pi_1(M_{p(x), R}) \rightarrow \pi_1(M_{p(x)})$ is surjective, we can find a path $\mu \in \tilde{x}$ such that $\text{Im } \mu \subset M_{p(x), R}$. Then the path $\gamma : [0, 1] \rightarrow M_{p(x), R}$ defined by $\gamma(t) = \mu(2t)$ for $t \in [0, \frac{1}{2}]$ and $\gamma(t) = x$ for $t \in [\frac{1}{2}, 1]$ is homotopic to μ , hence $\gamma \in \tilde{x}$. We define a continuous map $Z : U \times [0, 1] \rightarrow M$ as follows:

$$Z(y, t) = \begin{cases} G^{-1}(\mu(2t), p(y)) & \text{if } t \in [0, \frac{1}{2}], \\ G^{-1}(H(G_1(y), 2 - 2t), p(y)) & \text{if } t \in [\frac{1}{2}, 1] \end{cases}$$

We have then that $Z(y, t) \in M_{p(y)}$, $Z(y, 1) = y$ and $Z(y, 0) = \widehat{p(y)}$ for any $y \in U$, and $Z(x, t) = \gamma(t)$ for any $t \in [0, 1]$. Then \widetilde{U}_Z is a neighborhood of \tilde{x} and the restriction $\pi| : \widetilde{U}_Z \rightarrow U$ is a homeomorphism, where the notation \widetilde{U}_Z is defined as at (4). We have thus started with some point $\tilde{x} \in \pi^{-1}(x)$ and we have attached to it the map Z and the open neighborhood \widetilde{U}_Z ; since we want to compare in the following two such neighborhoods, let us denote \widetilde{U}_Z by $\widetilde{U}_{\tilde{x}}$.

In order to prove that U is evenly covered by π , it suffices to prove the following two statements:

- $\widetilde{U}_{\tilde{x}_1} \cap \widetilde{U}_{\tilde{x}_2} = \emptyset$ for $\tilde{x}_1, \tilde{x}_2 \in \pi^{-1}(x)$, $\tilde{x}_1 \neq \tilde{x}_2$,
- $\pi^{-1}(U) = \bigcup_{\tilde{x} \in \pi^{-1}(x)} \widetilde{U}_{\tilde{x}}$.

To prove (a) we let $\tilde{y}_0 \in \widetilde{U}_{\tilde{x}_1} \cap \widetilde{U}_{\tilde{x}_2}$ where $y_0 := \pi(\tilde{y}_0)$. Then there exist $\mu_1, \mu_2 : [0, 1] \rightarrow M_{p(x), R}$ with $\mu_1(0) = \mu_2(0) = p(x)$ and $\mu_1(1) = \mu_2(1) = x$ such that $[\mu_1] = \tilde{x}_1$, $[\mu_2] = \tilde{x}_2$, and that the paths $\nu_1, \nu_2 : [0, 1] \rightarrow M_{p(y_0), R}$ defined by

$$\nu_j(t) = \begin{cases} G^{-1}(\mu_j(2t), p(y_0)) & \text{if } t \in [0, \frac{1}{2}], \\ G^{-1}(H(G_1(y_0), 2 - 2t), p(y_0)) & \text{if } t \in [\frac{1}{2}, 1] \end{cases}$$

(for $j = 1, 2$) represent both \tilde{y}_0 and hence they are homotopically equivalent in $M_{p(y_0)}$. Moreover, they are homotopically equivalent in $M_{p(y_0), R}$ since the canonical morphism $\pi_1(M_{p(y_0), R}) \rightarrow \pi_1(M_{p(y_0)})$ induced by the inclusion is bijective (cf Lemma 2.8).

It follows that the two paths (for $j = 1, 2$):

$$t \rightarrow \begin{cases} \mu_j(2t) & \text{if } t \in [0, \frac{1}{2}], \\ H(G_1(y_0), 2 - 2t) & \text{if } t \in [\frac{1}{2}, 1] \end{cases}$$

are homotopically equivalent and therefore the paths μ_1 and μ_2 are homotopically equivalent. Hence $\tilde{x}_1 = \tilde{x}_2$ and (a) is proved.

To prove (b) we let $y_0 \in U$ and $\tilde{y}_0 \in \pi^{-1}(y_0)$. Since the canonical morphism $\pi_1(M_{p(y_0), R}) \rightarrow \pi_1(M_{p(y_0)})$ is surjective it follows that there exists $\nu \in \tilde{y}_0$ such that $\text{Im } \nu \subset M_{p(y_0), R}$. Let $\mu : [0, 1] \rightarrow M_{p(x), R}$ be defined by $\mu(t) = G_1(\nu(2t))$ if $t \in [0, \frac{1}{2}]$ and $\mu(t) = H(G_1(y_0), 2t - 1)$ if $t \in [\frac{1}{2}, 1]$. Let $\tilde{x} = [\mu]$. From the very definition if the following path:

$$\nu_1(t) = \begin{cases} \nu(4t) & \text{if } t \in [0, \frac{1}{4}], \\ G^{-1}((H(G_1(y_0), 4t - 1), p(y_0))) & \text{if } t \in [\frac{1}{4}, \frac{1}{2}], \\ G^{-1}(H(G_1(y_0), 2 - 2t), p(y_0)) & \text{if } t \in [\frac{1}{2}, 1] \end{cases}$$

we get that $[\nu_1] \in U_{\tilde{x}}$ and moreover that ν_1 and ν are homotopically equivalent. Hence $\tilde{y}_0 \in U_{\tilde{x}}$, which proves our claim. This ends the proof of Proposition 2.7 \square

2.4. End of the proof of Theorem 1.4. We use the following theorem proved by Meigniez, which is a nice generalization of a result by Palmeira [Pa].

Theorem 2.9. [Me2, Corollary 31]

A surjective smooth submersion with all fibres diffeomorphic to \mathbb{R}^p is a locally trivial fibration. \square

In our case fibers of $p \circ \pi : \widetilde{M} \rightarrow B$ are diffeomorphic to \mathbb{R}^2 , so this theorem implies that $p \circ \pi : \widetilde{M} \rightarrow B$ is a locally trivial fibration.

Let us recall the definition of a Serre fibration.

Definition 2.10. A map $\pi : E \rightarrow B$ between topological spaces is called a Serre fibration if for any simplex X , any homotopy $f : X \times [0, 1] \rightarrow B$ and \tilde{f}_0 a lifting of $f|_{X \times \{0\}}$, there exists a lifting $\tilde{f} : X \times [0, 1] \rightarrow E$ of f such that $\tilde{f}|_{X \times \{0\}} = \tilde{f}_0$.

Since $\pi : \widetilde{M} \rightarrow M$ is a covering and $p \circ \pi : \widetilde{M} \rightarrow B$ is a locally trivial fibration, both are Serre fibrations. It then follows that $p : M \rightarrow B$ is a Serre fibration (which is straightforward, see also [Me2, Example 38]).

In order to conclude, we need another result by Meigniez:

Proposition 2.11. [Me2, Corollary 32]

Suppose that E and B are smooth manifolds such that $\dim_{\mathbb{R}} E = \dim_{\mathbb{R}} B + 2$ and $\pi : E \rightarrow B$ is a surjective smooth map. If π is both a submersion and a Serre fibration then $\pi : E \rightarrow B$ is a locally trivial fiber bundle. \square

Applying this proposition to our submersive Serre fibration $p : M \rightarrow B$, we deduce that it is a locally trivial fibration. Theorem 1.4 is now proved. \square

Note that this also proves Theorem 1.3 in case that the fibres $p^{-1}(t)$ of the holomorphic map p are connected for any t in some small neighborhood of λ . In the next section we shall prove the general result.

We end this section by two simple examples which illustrate the importance of the hypotheses of Theorem 1.4.

EXAMPLE 2.12. Let $M = \mathbb{C}^2 \setminus (\{(z, w) \in \mathbb{C}^2 \mid zw = 1\} \cup \{0\})$ and let $p : M \rightarrow \mathbb{C}$ be the projection on the first coordinate. Then p is a surjective submersion, all fibers are diffeomorphic to \mathbb{C}^* but obviously this is not a locally trivial fibration. M is not Stein.

If $\gamma_n : [0, 1] \rightarrow \mathbb{C}^2$, $\gamma_n(t) = (\frac{1}{n}, e^{2\pi it})$ for $n \geq 2$, and $\gamma : [0, 1] \rightarrow \mathbb{C}^2$, $\gamma(t) = (0, e^{2\pi it})$ then γ_n is homotopically trivial in $p^{-1}(\frac{1}{n})$, γ_n converges uniformly to γ but γ is not homotopically trivial in $p^{-1}(0)$. We have here a non-trivial vanishing cycle in the terminology of Meigniez's [Me2]. If we apply Ilyashenko's construction to this setting then the topology of \widetilde{M} will be not separated. We also have another "cycle vanishing at infinity" in the terminology of [Ti2].

EXAMPLE 2.13. Let $M = \mathbb{C}^2 \setminus (\bigcup_{n \in \mathbb{N}} \{(z, w) \in \mathbb{C}^2 \mid w = n\} \cup \{(z, w) \in \mathbb{C}^2 \mid z = w\})$ and let $p : M \rightarrow \mathbb{C}$ be the projection on the first coordinate. Then p is a surjective submersion, all fibers are diffeomorphic to $\mathbb{C} \setminus \mathbb{N}$, and M is Stein. However p is not a locally trivial fibration. In the terminology of [Me2], non-trivial emergent cycles occur around the origin. This satisfies Ilyashenko's theorem but not the finiteness of the Betti numbers of fibres condition of Theorem 1.4.

3. PROOF OF THEOREM 1.3

After proving Theorem 1.3 in the particular case of connected fibres, let us now treat the general case.

Let $p : M \rightarrow B$ be a holomorphic map between connected complex manifolds such that M is Stein, $\dim M = \dim B + 1$, and the Betti numbers $b_0(t)$ and $b_1(t)$ of all the fibers $p^{-1}(t)$ are finite. Let λ be a point in the interior of the set $\text{Im } p \setminus \overline{p(\text{Sing } p)} \subset B$. We assume that the Euler characteristic of the fibres is constant for t varying in some neighborhood of λ and no connected component of $p^{-1}(t)$ is vanishing at infinity when $t \rightarrow \lambda$.

Let \mathcal{C}_t be the set of connected components of the fibre $p^{-1}(t)$, which is by hypothesis a finite set with $b_0(t)$ elements, and let $b_0(\lambda) = b_0$.

Let $\{C_1, \dots, C_{b_0}\}$ denote the connected components of $p^{-1}(\lambda)$. Choose and fix some point $x_j \in C_j$, for any j . Since p is a submersion over some small neighborhood of λ , we may choose some mutually disjoint small balls $B_j \subset \mathbb{C}^{n+1}$ centered at x_j , and some small enough ball $D \subset B$ centered at λ such that the intersection $B_j \cap p^{-1}(\lambda)$ is connected and that the restriction

$$(6) \quad p|_{B_j \cap p^{-1}(D)} : B_j \cap p^{-1}(D) \rightarrow D$$

is a trivial C^∞ -fibration for any $j \in \overline{1, b_0}$.

We then define $a_t(j)$ as the connected component of $p^{-1}(t)$ which intersects $B_j \cap p^{-1}(D)$. This yields a well defined function $a_t : \{1, \dots, b_0\} \rightarrow \mathcal{C}_t$ since $B_j \cap p^{-1}(t)$ is itself connected for any $t \in D$ and any j , by (6).

Lemma 3.1. *The Betti numbers $b_0(t)$ and $b_1(t)$ of the fibre $p^{-1}(t)$ are constant for t in some small neighborhood of λ .*

Proof. We claim that the function a_t is surjective, for any t in some small neighborhood of λ . If not so, then there is a sequence $t_i \rightarrow \lambda$ and some connected component C^{t_i} of $p^{-1}(t_i)$ which does not intersect any ball B_j , for $j \in \overline{1, b_0}$. By the assumed non-vanishing condition (NV) at λ , there exists some compact $K \subset M$ such that $C^{t_i} \cap K \neq \emptyset$ for any $i \gg 1$. (We actually get this possibly after passing to an infinite sub-sequence of sets $C^{t_{i_p}}$.) Let us then fix some point $z_{t_i} \in C^{t_i} \cap K$. We may assume, again after passing to a sub-sequence, that z_{t_i} tends to some limit point $z_0 \in K$. Consequently, $\lim_{i \rightarrow \infty} p(z_{t_i}) = p(z_0) = \lambda$. Since $z_0 \in C_1 \cup \dots \cup C_{b_0}$, there is some $j_0 \in \overline{1, b_0}$ such that $z_0 \in C_{j_0}$. By taking a simple path linking x_{j_0} to z_0 within C_{j_0} and by considering a tubular neighborhood of it in M , we may assume, by using Ehresmann's theorem, that there exists a connected open set \mathcal{N}_{j_0} containing z_0 and x_{j_0} such that the intersection $\mathcal{N}_{j_0} \cap p^{-1}(\lambda)$ is connected and that the restriction:

$$(7) \quad p| : \mathcal{N}_{j_0} \cap p^{-1}(D) \rightarrow D$$

is a trivial C^∞ -fibration (possibly after shrinking the ball D), and therefore all its fibres are connected.

Since \mathcal{N}_{j_0} is open and contains z_0 , it contains the points $z_{t_i} \in C^{t_i}$ for sufficiently large index $i \in \mathbb{N}$. Hence for $i \gg 1$ the connected set $p^{-1}(t_i) \cap \mathcal{N}_{j_0}$ is contained in C^{t_i} and on the other hand $B_{j_0} \cap \mathcal{N}_{j_0} \cap p^{-1}(D) \neq \emptyset$.

Since we have assumed that $C^{t_i} \cap B_{j_0} = \emptyset$, we thus get a contradiction. Our surjectivity claim is proved. In particular, we have $b_0(t) \leq b_0(\lambda)$ for t in some small neighborhood of λ .

By Proposition 2.4, possibly after shrinking D , we also have $b_1(t) \geq b_1(\lambda)$. We therefore get:

$$\chi(t) = b_0(t) - b_1(t) \leq b_0(\lambda) - b_1(t) \leq b_0(\lambda) - b_1(\lambda) = \chi(\lambda)$$

and since $\chi(\lambda) = \chi(t)$ by our hypothesis, we deduce that the Betti numbers $b_0(t)$ and $b_1(t)$ are constant at λ . \square

In particular, from the equality $b_0(t) = b_0(\lambda)$ proved in Lemma 3.1 we deduce that the function a_t is bijective, for t in some small enough neighborhood of λ . We may therefore denote from now on $C_j(t) := a_t(j)$, $j \in \overline{1, b_0}$.

Keeping the above notations, we moreover have the following result showing that the connected components belong to families:

Lemma 3.2. *The union $V_j := \bigcup_{t \in D} C_j(t)$ is an open set in M , for any $j \in \overline{1, b_0}$.*

Proof. Let $y_0 \in C_j(t_0)$ for some $t_0 \in D$. Let \hat{D} be the section of the trivial fibration (6) which contains the center $x_j \in C_j(\lambda)$ of the ball B_j , and let $z_0 := C_j(t_0) \cap \hat{D}$. We consider a simple path within $C_j(t_0)$ connecting z_0 to y_0 . Like in the proof of Lemma 3.1, one may find a connected open tubular neighborhood $\mathcal{N}_j \subset M$ of this path such that $\mathcal{N}_j \cap p^{-1}(t_0) = \mathcal{N}_j \cap C_j(t_0) \subset V_j$ is connected and that the restriction:

$$(8) \quad p| : \mathcal{N}_j \cap p^{-1}(D_0) \rightarrow D_0$$

is a trivial C^∞ -fibration, where $D_0 \subset D$ is some small enough ball centered at $t_0 \in \mathbb{C}^n$. Since \mathcal{N}_j contains by definition some neighborhood of z_0 , the intersection $\mathcal{N}_j \cap \hat{D}$ contains a neighborhood of z_0 in \hat{D} . It then follows from the definition of the components $C_j(t)$

that the fibers of the fibration (8) must be subsets of V_j , after possibly shrinking D_0 . And since the neighborhood $\mathcal{N}_j \cap p^{-1}(D_0)$ is included in V_j , it contains by definition a small ball around y_0 . \square

We may now finish the proof of Theorem 1.3. By the definition of V_j and the fact that the functions a_t are bijections for all $t \in D$, we get that the union $\bigcup_{j=1}^{b_0} V_j$ is a disjoint union of connected components and it is equal to $p^{-1}(D)$, and that $p(V_j) = D$, $\forall j \in \overline{1, b_0}$. Since D is Stein it follows that each V_j is Stein. Therefore $p|_{V_j} : V_j \rightarrow D$ is a submersion with connected 1-dimensional fibers $C_j(t)$ on the Stein manifold V_j .

By Proposition 2.4 there exists an open neighborhood D' of λ , $D' \subset D$, such that we have $b_1(C_j(t)) \geq b_1(C_j)$ for $t \in D'$. We may assume without loss of generality that this holds for the same D' for any $j \in \overline{1, b_0}$. Since we have proved that the total first Betti number is constant, i.e. $\sum_{j=1}^{b_0} b_1(C_j(t)) = \sum_{j=1}^{b_0} b_1(C_j)$, we obtain the constancy on every component, i.e. $b_1(C_j(t)) = b_1(C_j)$, $\forall j \in \overline{1, b_0}$. We then apply Theorem 1.4 to the restriction $p|_{V_j \cap p^{-1}(D')}$ and get that it is a trivial fibration $\forall j \in \overline{1, b_0}$. Therefore p is a trivial fibration.

4. SOME CONSEQUENCES

Corollary 4.1. *Let $p : M \rightarrow B$ be a holomorphic map between connected complex manifolds, where M is Stein with $\dim M = \dim B + 1$, and the fibers of p have finitely generated fundamental group. Let λ be a point in the interior of the set $\text{Im } F \setminus \overline{F(\text{Sing } F)} \subset \mathbb{C}^n$.*

- (a) *Assume that for t in some neighborhood of λ the fibers $p^{-1}(t)$ have constant Euler characteristic and the Betti number b_1 of each of their components is at least 2. Then f is a locally trivial fibration at λ .*
- (b) *Assume that for t in some neighborhood of λ the fibers $p^{-1}(t)$ have constant Betti numbers $b_0(t)$ and $b_1(t)$ and the Betti number b_1 of each of their components is at least 1. Then f is a locally trivial fibration at λ .*

Proof. (a). We use the construction and the notations in the proof of Proposition 2.4, from which we recall the following: let $\mathcal{C}_\lambda = \{C_1, \dots, C_{b_0}\}$ be the set of connected components of the fibre $p^{-1}(\lambda)$, where $b_0 := b_0(\lambda)$. We chose a holomorphic function $f : M \rightarrow \mathbb{C}$ such that $f|_{C_j} \equiv 2j$, for any $j \in \{1, \dots, b_0\}$. We defined $U_1 = \{x \in M \mid \text{Re}(f(x)) < 3\}$, $U_j = \{x \in M \mid 2j - 1 < \text{Re}(f(x)) < 2j + 1\}$ for $j \in \{2, \dots, b_0 - 1\}$, $U_{b_0} = \{x \in M \mid \text{Re}(f(x)) > 2b_0 + 1\}$, where $\text{Re}(f)$ denotes the real part of f . We chose smooth strictly plurisubharmonic exhaustion functions $\varphi_j : U_j \rightarrow \mathbb{R}$, sufficiently large real numbers $r_j \gg 1$, and a connected open neighborhood B' of λ such that the restrictions $p| : p^{-1}(B') \cap \{y \in U_j \mid \varphi_j(y) < r_j\} \rightarrow B'$ are trivial C^∞ -fibrations with connected fibres.

Fixing some $t \in B'$, let $\mathcal{C}_t = \{\Gamma_1, \dots, \Gamma_q\}$ be the set of connected components of $p^{-1}(t)$. We have defined the function $\beta : \mathcal{C}_\lambda \rightarrow \mathcal{C}_t$ by $\beta(C_j) :=$ the unique connected component of \mathcal{C}_t which intersects $\{y \in U_j \mid \varphi_j(y) < r_j\}$. By changing the indices we may assume that $\beta(C_1) = \dots = \beta(C_{n_1}) = \Gamma_1, \dots, \beta(C_{n_{q'-1}+1}) = \dots = \beta(C_{b_0}) = \Gamma_{q'}$ where $q' \leq q$ and $1 \leq n_1 < n_2 < \dots < n_{q'-1} < b_0$. Finally, in the proof of Proposition 2.4 we obtained the inequality: $\sum_{j=1}^{q'} b_1(\Gamma_j) \geq b_1(\lambda)$.

Since by our hypothesis $b_1(\Gamma_j) \geq 2$ for every $j \in \{1, \dots, q\}$ and, in particular, for $j \in \{q' + 1, \dots, q\}$, we obtain that $b_1(t) \geq b_1(\lambda) + 2(q - q')$. By our hypothesis we have $\chi(t) = \chi(\lambda)$ and hence $b_1(t) = b_1(\lambda) - b_0 + q$, since $q = b_0(t)$ by definition. This yields $b_1(\lambda) - b_0 + q \geq b_1(\lambda) + 2(q - q')$ and hence $2q' \geq b_0 + q$.

Since by our construction we have $q' \leq q$ and $q' \leq b_0$, we conclude that the equalities $b_0 = q$ and $q = q'$ must hold. This shows in particular that we have “non-vanishing of components” at λ . We may now apply Theorem 1.1 to conclude.

(b). The same arguments as at (a), but instead of $b_1(\Gamma_j) \geq 2$ we have now by hypothesis $b_1(\Gamma_j) \geq 1$ and $b_0 = q$. We thus obtain the inequality $b_1(t) \geq b_1(\lambda) + (b_0 - q')$.

Since $b_1(t) = b_1(\lambda)$ by hypothesis, we get $q' \geq b_0$. Since $b_0 \geq q'$ by construction, we must have equality $b_0 = q'$, thus non-vanishing of connected component and we conclude by applying Theorem 1.3. \square

For a polynomial map $F = (F_1, \dots, F_n) : \mathbb{C}^{n+1} \rightarrow \mathbb{C}^n$, we denote by $\chi(t)$ the Euler characteristic of the fibre $F^{-1}(t)$ and by \overline{F}_t the closure of the fibre $F^{-1}(t)$ in \mathbb{P}^{n+1} in some fixed system of coordinates.

Corollary 4.2. *Let $F = (F_1, \dots, F_n) : \mathbb{C}^{n+1} \rightarrow \mathbb{C}^n$ be a polynomial map and let λ be an interior point of the set $\text{Im } F \setminus \overline{F(\text{Sing } F)} \subset \mathbb{C}^n$. If the degree $\deg \overline{F}_t$ and the Euler characteristic $\chi(t)$ are constant for t varying in some neighborhood of λ , then $\lambda \notin B(F)$.*

Proof. Since $\deg \overline{F}_t$ is constant, it follows that the number of intersection points $F_t \cap H$, where $H \subset \mathbb{C}^{n+1}$ is a general hyperplane, is constant, for all t close to λ . We show that this implies (NV) at λ .

By our hypothesis, the hyperplane H intersects all component of F_t . If not (NV) at λ , then there is a component which is “lost” at infinity, hence there is at least some point $p \in F_t \cap H$ which tends to infinity when $t \rightarrow \lambda$, which just means that the restriction $F|_H$ is not proper. The number of intersection points $F_t \cap H$ is a locally semicontinuous function in the sense that this number cannot locally increase in the limit whenever the limit of points exists in F_λ . In our case there is at least a path γ consisting of such intersection points $\gamma(t) \in F_t \cap H$, such that $\|\gamma(t)\| \rightarrow \infty$ as $t \rightarrow \lambda$. This yields the contradiction. We may conclude by applying Theorem 1.1. \square

REMARK 4.3. The above statement has been proved in [HN, Corollary 2.2] in the particular case when the zero locus at infinity $Z((F_1)_{d_1}, \dots, (F_n)_{d_n}) \cap H_\infty$ of the homogeneous parts $(F_i)_{d_i}$ of the highest degree d_i of F_i is of dimension zero. In this case we have the constancy of the degree $\deg(\overline{F}_t) = d_1 \cdots d_n$ for every t in a neighborhood of λ .
